Abstract

This report is a summary of the "Love Letter" game for Software Engineering classes at French-Azerbaijani University (UFAZ). This project is intended to put into practice the knowledge and techniques acquired in the course of Software Engineering. The task is to propose an implementation of "Love Letter" - card game which is played by 2 to 4 players. In this report, a brief information about software engineering topics, game manual and our progress is given, and UML diagrams along with Agile reports are demonstrated.

INTRODUCTION

PURPOSE

This project is intended to put into practice the knowledge and techniques acquired in the course of Software Engineering. Project allow us to experiment with new topics, techniques and tools. The purpose of this project is to propose an implementation of “Love Letter” - card game which is played by 2 to 4 players. The rules that we respected during implementation phase are described in “Design & Specification” stage(Look at [2](#)).

OBJECTIVES

- Practice and improve ourselves on various areas of software development
- Gain skills in developing effective software
- Practice with Agile methods
- Develop effective teamwork skills
- Propose an implementation of Love Letter - card game
- Demonstrate as much as possible the qualities of a good Man-Machine Interface
- Localize interface for at least two countries speaking different languages
- Form a coherent "whole" User Interface
- Implement Artificial Intelligence module for game
- Make application responsive for mobile
- Implement continues integration and deployment
- Implement unit tests
- Write detailed and quality report
- Propose user manual and graphs

DESCRIPTIONS

Software Project : Software engineering is an engineering branch associated with development of software product using well-defined scientific principles, methods and procedures. The outcome of software engineering is an efficient and reliable software product.

A software development project is a complex undertaking by several persons within the boundaries and staff resources that produces new or enhanced computer code.

Software project management is essential to incorporate user requirements along with budget and time constraints. The image on the right shows triple restrictions for software projects. It is an essential part of software organization to deliver **quality** product, keeping the **cost** within client's budget constrain and deliver the project **in time**.

A Software Project is the complete procedure of software development from requirement gathering to testing and maintenance, carried out according to the execution

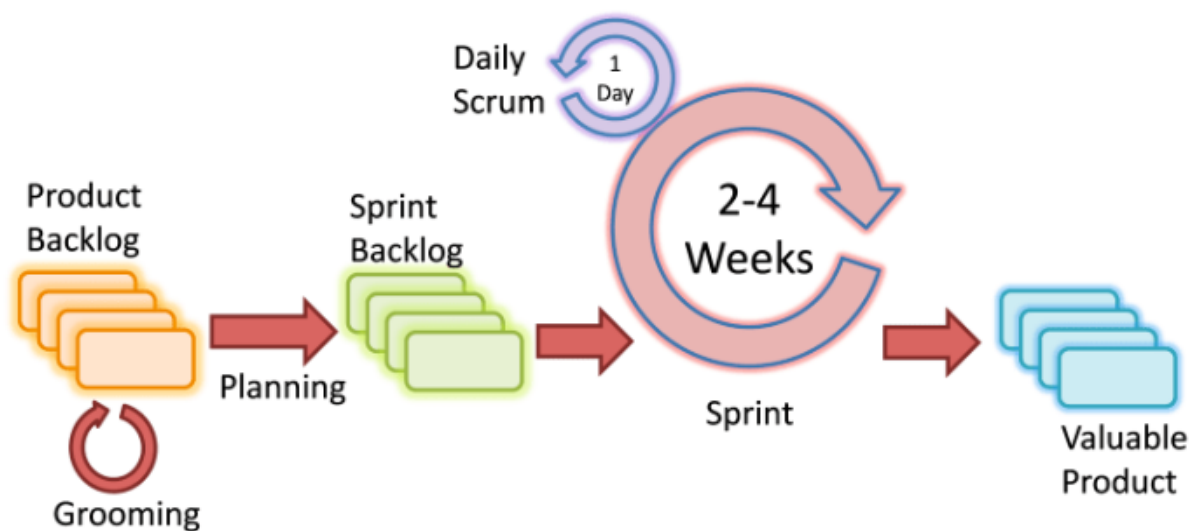

methodologies, in a specified period of time to achieve intended software product. During the lifecycle of a project, some particular entities can be distinguished:

- The **customer** is the one who **expresses the need**.
- The **supplier** is the one who **meets the need**.
- The **stakeholder** is the one who has any interest in project's outcome. Other than customer and supplier, it is typically members of a project team, project managers, executives, project sponsors, and users.

Software Development Life Cycle Model : SDLC model - is a series of phases that provide a common understanding of the software building process. How the software will be realized and developed, and requirements elicitation phase to convert these ideas and requirements into functions and features until its usage and operation to achieve the needs. It is important to choose the right SDLC model according to the specific concerns and requirements of the project to ensure its success.

Agile Model : The agile method involves breaking down project into prioritized requirements, and delivering each individually within an iterative cycle. An iteration is the routine of developing small sections of a project at a time. Each iteration is reviewed and assessed by the development team. The insights gained from the assessment are used to determine the next step in development. Detailed goals are set in each iteration meeting such as: expected changes, time estimates, priorities. Agile project methodology breaks down projects into small pieces that are completed in work sessions or sprints that run from the design phase to testing. Sprints are generally short, running over days or weeks.

Unit Testing : UT - is the first level of software testing where individual units/ components of a software are tested. The purpose is to validate that each unit of the software performs as designed. A unit is the smallest testable part of any software. Unit Testing is performed prior to Integration Testing.

Continuous Integration : CI - s the practice of automating the integration of code changes from multiple contributors into a single software project. By integrating regularly, it is possible to detect errors quickly, and locate them more easily. Additionally, Continuous Deployment and Continuous Delivery have developed as best-practices for keeping your application deployable at any point or even pushing your main codebase automatically into production whenever new changes are brought into it. This allows your team to move fast while keeping high quality standards that can be checked automatically.

Project Life Cycle : A project life cycle is the sequence of phases that a project goes through from its initiation to its closure.

Needs Analysis:

Data collecting. Redefining real needs by understanding the context and analyzing needs expressed by the client.

Specification:

Describing previously analyzed needs with more details in the form of requirements that the solution must imperatively satisfy.

Design:

Providing the solution that meet all the requirements identified during specification phase.

Implementation:

Implementing the solution conceived during design phase.

Testing:

Testing the software, to improve its quality and to know the degree of presence of a particular quality.

Deployment:

Delivering the software into production, making it available to the end user.

Maintenance::

Modifying the current software, adding new functionalities, preventing anomalies.

DESIGN & SPECIFICATION

USER MANUAL

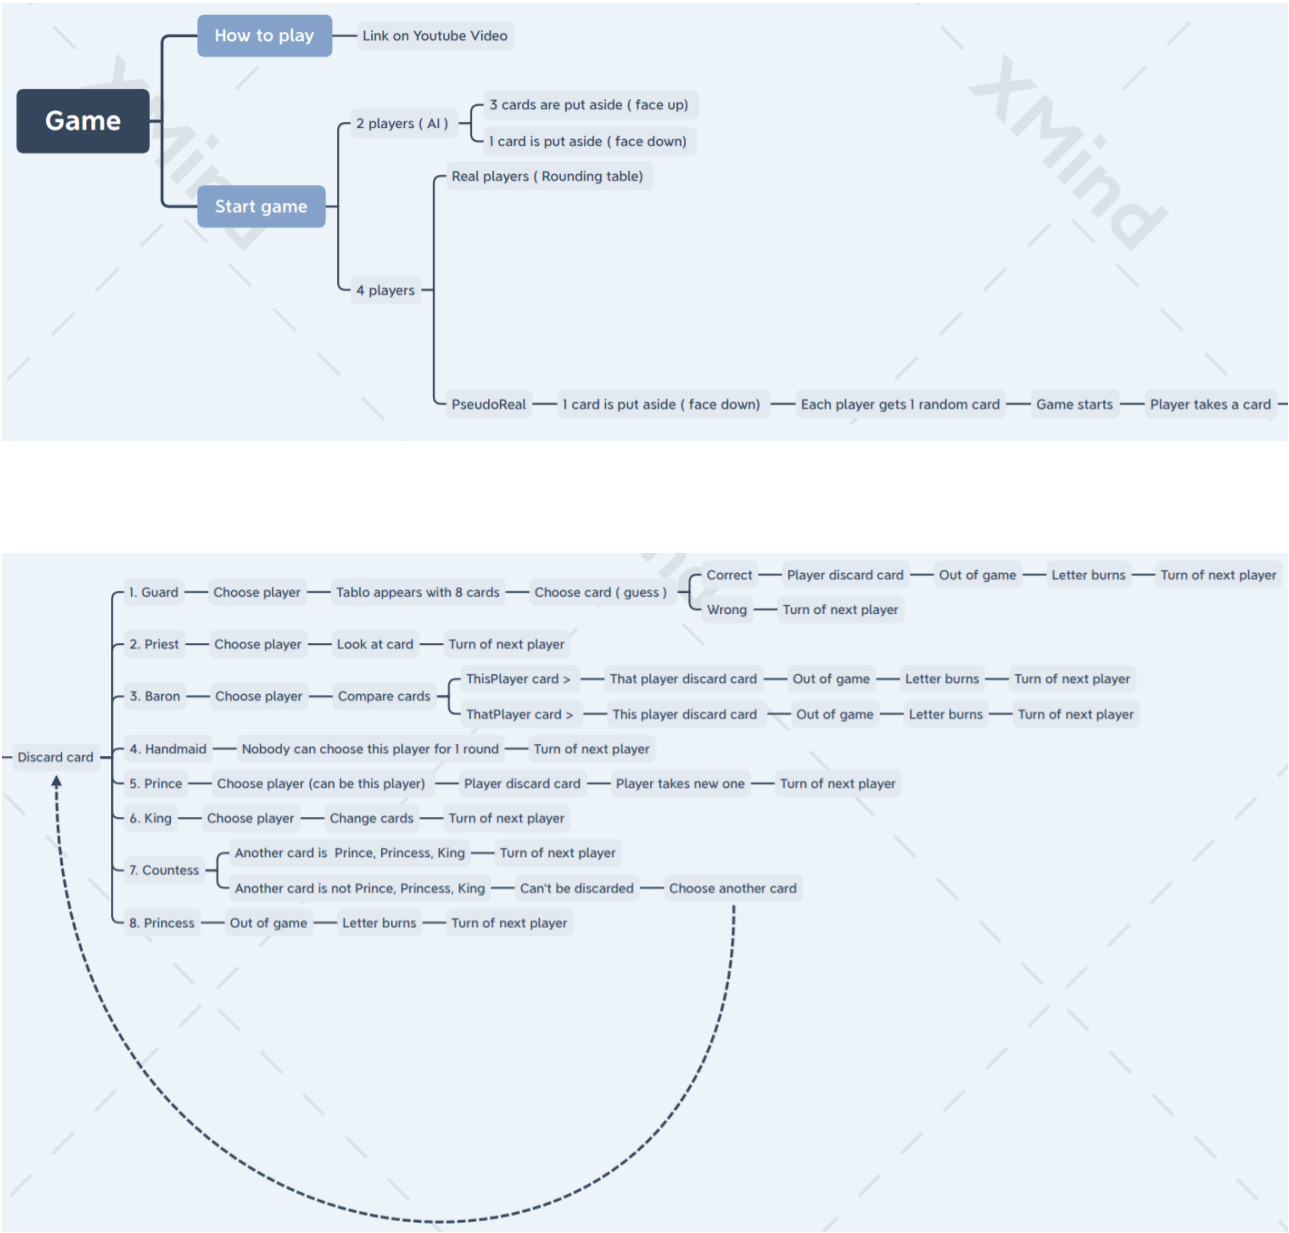

Figure 2.1: Game Model

HOW IT WORKS?

As the game app launches player can choose the preferred interface language (**English, French, Azerbaijani or Russian**). If player does not know anything about the rules, he can click “How to play?” button and watch the video to learn and then click “Start Game”. Otherwise, he can start the game directly.

After clicking “Start Game”, player can choose the number of players (from 2 to 4) and their levels (easy or medium). For now, only easy level is available. Medium will be ready soon. When player clicks “Launch the game” button, cards are distributed to the number of players selected. If game starts with 2 players, then **1 unknown and 3 known cards** are reserved. In other cases, **1 unknown card is reserved**.

Player can click on “Show all cards” button to become more familiar with each card’s abilities. As player clicks on “Start your turn” button, he gets randomly distributed card from card deck. Each player has “**brain**” property and during each round players’ actions are being written to the “brain” and these actions are considered in the players’ next turns. With respect to the game rules, as the “brain” compares the previously distributed players’ cards, it decides which cards will be distributed next for the game to be logically correct and interesting.

The game proposes the following scenario and rules. For example:

- If player chose to play with “Guard” card, he must choose the player and try to predict his card. If the prediction is correct, chosen player loses the round.
- Choosing to play the “Priest” card gives the player the ability to look at other player’s card for 3 seconds.
- As player chooses the “Baron” card, he can compare his cards with the other player. The player, with lower card value loses the round. If the card values are the same, player with lower sum of values of discarded cards loses the round.
- Playing the “Handmaid” card gives player an advantage of ignoring other players actions until the next turn.
- Playing the “Prince” card, you can choose yourself or the other player to discard his card and draw another one.
- If player chooses the “King” card, he can choose the player to exchange his cards with him.
- If player has the “Countess” card along with “King” or “Prince” card, he has to discard the “Countess” card. If player will not do so, he loses the round.
- Getting the “Princess” card, player should not discard it. If player did so, he loses the round.

At the end of each turn, player can see the actions played by AI in a dashboard to be able to think about the further strategy of the game.

During the game, player can see the number of won rounds of each player.

TEAM AND PROJECT ORGANIZATION

SPRINTS

First, we divided the project into 5 sprints and were planning to start working on the project on the April 1. We were aiming to spend two weeks for each sprint. Unfortunately, due to some unpredicted time issues, the start date was delayed to April 20. Therefore, each sprint was reduced to one week time frame.

The project was divided into 5 following sprints: Project Initialization (April 23- May 30), Development Phase 1 (May 1-May 5), Development Phase 2 (May 6-May 11), Testing (May 12-May 17), Project closure (May 18-22).

1. Sprint 1. Project Initialization. Initial meetings, dicussions, planning and task assignments.(Figure 4.1)

Figure 4.5: Issues and tasks of Sprint 5 - Project Closure

TEAM MEMBER ROLES

Due to the short time limit, the tasks were assigned for each of us based on our skills in order to carry the workflow efficiently, smooth and speedily. We tried to ensure that our group is functional, that everyone can do their share of the work, in a way that suits their desires and abilities.

- Taking into account Murad's experience in back-end and devops, he was responsible with logic implementation and AI implementation, and setting up server for deployment. He was the one who distributed assignments and tasks among group members, carried out project report, set up and managed "Bitbucket" control repository hosting service. Murad cooperated in front-end and language localisation either.
- According to Farid's expertising field, he was assigned mainly front-end related tasks, such as, adding animations, visual effects, general appearance of the game, development of small components(dashboard, informative panels). He also contributed in setting up language localisation.
- Ofelia enhanced front-end by making the game responsive on all devices, such as laptops, tablets, mobile phones. She is the author of the full game design as well. UML diagrams and some tables were prepared by Ofelia that are in project report.
- Saida supported the project by contributing to game logic, providing necessary information for game and project development. Development of the project report was carried out mainly by Saida and Murad, partly by Farid and Ofelia.

TECHNOLOGIES USED

There are optional and mandatory tasks for this project. We had to choose to implement either artificial intelligence or networking, or to propose a solution to allow several humans to play locally, on the same screen. All our team members has a lot of interest to Artificial Intelligence, but we could never try ourselves in this area. And also we had a lot of practice with networking on the past, so we decided to go with a new style. Because of time restriction, and a little experience on back-end between team members, we decided to avoid using back-end. So we came to decision to render all project on client-side, without using back-end and database. The only restriction is that, all data is cleaned up on page refresh.

TOOLS

- HTML5

HTML is used for structuring and presenting content on browser. HTML5 was the fifth and last major version of HTML that is a World Wide Web Consortium (W3C) recommendation.

- CSS3

CSS is used as a style sheet language used for describing the presentation of a document. CSS3 is the latest evolution of the Cascading Style Sheets language.

- jQuery3.5

jQuery is a JavaScript library which we used to simplify HTML DOM tree traversal and manipulation, as well as event handling, CSS animation, and Ajax.

- JS

JavaScript is the most popular implementation of the ECMAScript Standard. The core features of Javascript are based on the ECMAScript standard, but Javascript also has other additional features that are not in the ECMA specifications/standard. We used Vanilla JS along with jQuery in order to manipulate HTML DOM tree.

- EcmaScript

ECMAScript(or ES) is a scripting-language specification standardized by Ecma International. It was created to standardize JavaScript to help foster multiple independent implementations. ES modules bring an official, standardized module system to JavaScript. ES module files are loaded using the standard Same-Origin policy restrictions that browsers enforce and have many other security restrictions in place, while JavaScript "script" files have much more lax security to avoid breaking existing websites as better security standards have been added to browsers over time.

We built custom state management system and JS library in order to easily build our user interface.

- Python3

Python is used to in order to set up HTTP server for our EcmaScript project,

- Git / BitBucket

Git is used as distributed version control system during software development lifecycle. Bitbucket is used as a repository hosting for our software. There are several good repository hosting services, but we decided to go with Atlassian products, so that we can easily connect our repository to our project management software. Besides that, Bitbucket much more simple setup, easily configured pipelines for continues integration and deployment and nice ui and different tools which makes version control much more easier.

- Jira

There are a lot of product management tools on the market. But with current experience, we decided that Jira is the most suitable for Agile Project Management.

- Heroku

Heroku is a platform as a service (PaaS) that enables developers to build, run, and operate applications entirely in the cloud. We decided to go with Heroku because it gives free plan and it is very easy to configure. It also provides you with built-in CLI and ssh access.

ISSUES

- Game is not supported on some versions of Safari, as old IOS versions doesn't have EcmaScript support.
- Because of browser rendering, there can be some problems if game is played quickly, please consider waiting for a second between actions,

CONCLUSIONS

WHAT WE LEARNT?

Nowadays most of the things has it is online equivalent, and one of the popular products in virtual world is board games which easily replaces face-to-face games. The board game industry has seen a resurgence in recent years and is expected to carry on growing further. Thus, working on “Love Letter” game gave us valuable knowledge and experience in a various areas.

Throughout the procedure of the project development, formation of web applications has been profusely practiced, hence sharpening our coding skills. Withal, we had an opportunity to have first-hand knowledge of the beauty of working on real-life project, as well as facing the difficulties of efficient cooperation. We predominantly worked on the core principals of the team development, which allowed us to easily communicate, as well as respect each other’s opinion while making significant decisions that has huge impact on project’s success. The main aspects we worked on were bringing the whole team to one vision, making team to work as one, making everyone to have the same end goal and to help each other to reach it.

We investigated the characteristics of a good software system, and considered what a development process would need to include to build such software.

Being a small team of 4 members, choosing “Agile” as a Software Development Life Cycle model to deliver qualitative project on time using resources we have, seemed appropriate to us, as it has a lot of advantages which facilitated our work. This method allowed us to learn a lot of new things, to adapt to conditions, to focus on essentials during each iteration. Despite the fact that while setting up the development process we’ve met some difficulties, the chosen model was efficient for us.

WHAT WE DID?

As a result of our project we did:

- Practiced and improved ourselves on various areas of software development
- Gained skills in developing effective software
- Practiced with Agile methods
- Developed effective teamwork skills
- Proposed an implementation of Love Letter - card game
- Demonstrated as much as possible the qualities of a good Man-Machine Interface
- Localized interface for 4 languages
- Formed a coherent "whole" User Interface
- Implemented Artificial Intelligence module for game
- Made application responsive for mobile
- Implemented continues integration and deployment
- Implemented unit tests
- Wrote detailed and quality report
- Proposed user manual and graphs

RESULT

The developed "Love Letter" game can be accessed by visiting:
<https://loveletterapp.herokuapp.com/>
